ABSTRACT: This study presents results from several expeditions in 1985, 1991-1995 and 2003 to the Medium Paraná River in the section that begins below the Itaipu Dam and ends at the trinational border of Brazil, Argentina and Paraguay, in the lotic and lentic zones of the reservoir of the Hydroelectric Power Station of "Itaipu Binacional" (localities Foz do Iguaçu, Santa Helena and Guaira). Ninety-eight species of freshwater fishes belonging to 22 families were examined for helminths. A host-parasite list based on Acanthocephala, Cestoda, Digenea, Monogenea and Nematoda collected from the region in question is provided. New host records are presented for Digenea and Nematoda. The Monogenea and Acanthocephala are being studied and will be published in a later paper, but are referred in the host-parasite list, in order to demonstrate the parasitism in the fishes of the reservoir. The results are compared with those presented by other authors from the Upper Paraná River.

Introduction

The Paraná River, the tenth longest river in the world, is a river in south-central South America, running through Brazil, Paraguay and Argentina. Together with its tributaries, it forms the larger of the two river systems that drain into the La Plata River, making it the second largest river system in South America, outranked only by the Amazon River. Along the course of the Paraná is the Itaipu Dam, the largest hydroelectric power station in the world, which creates a massive, deep reservoir behind it. Itaipu Binacional is a binational company undertaking run by Brazil and Paraguay at the Paraná River on the border section between the two countries.

Fish parasites in the Medium Paraná River basin have remained little known to date. This study reports results from several expeditions in 1985, 1991-1995 and 2003 to the Medium Paraná River in the section that begins below the Itaipu Dam and ends at the trinational border of Brazil, Argentina and Paraguay, and in the reservoir of the Hydroelectric Power Station of Itaipu Binacional, in the localities of Foz do Iguaçu (lentic zone, next to the dam at the end of the reservoir), Santa Helena (transition zone in the middle of the reservoir) and Guaira (lotic zone at the beginning of the reservoir) (Figure 1). A host-parasite list is presented in Table 1. The results were compared with those obtained by other authors in the floodplain of the Upper Paraná River and recently published in a checklist by Takemoto et al. (2009).

MATERIALS AND METHODS

A total of 1,142 freshwater fish specimens belonging to 98 species and 22 families were examined for helminths. These were caught using gill nets in the Medium Paraná River in the localities of Foz do Iguaçu (25°32'52"

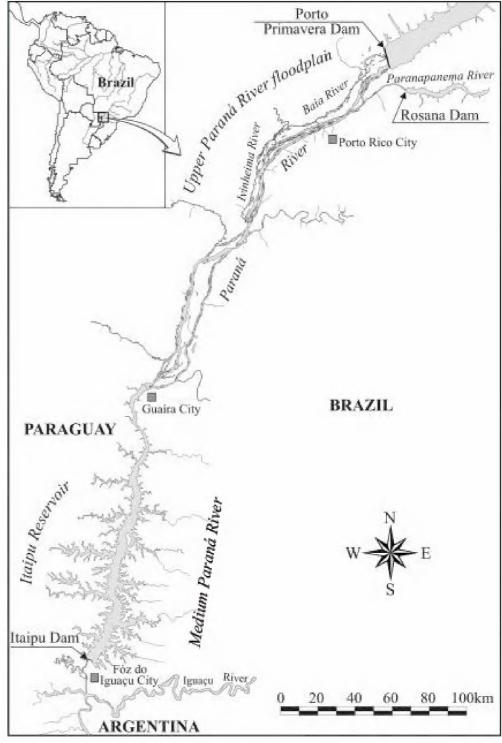

FIGURE 1. Location of the Medium Paraná River with the reservoir of the Hydroelectric Power Station of Itaipu and Upper Paraná River floodplain, Brazil.

N, 54°35'17" W), lentic zone, at the end of the Itaipu reservoir of the Hydroelectric Power Station of Itaipu Binational, Paraná State, Brazil; Santa Helena (24°51'37" N, 54°19'58" W), transition zone, in the middle of the reservoir; and Guaira (24°04'48" N, 54°15'21" W), lotic zone, at the beginning of the reservoir. Parasites collected were processed in accordance with the methodology used for each group. The names of fishes accepted as valid follow the most recent bibliography (Froese and Pauly 2010; Graça and Pavanelli 2007) and sometimes do not correspond to the names of parasite references. Material studied was deposited in the Helminthological Collection of the Oswaldo Cruz Institute, Fiocruz, Rio de Janeiro, Brazil.

RESULTS AND DISCUSSION

Of the 98 fish species examined from the Medium Paraná River, lotic and lentic zones of the reservoir of the Hydroelectric Power Station of Itaipu, parasitism by helminths was verified in 78 species. Nematoda was the most prevalent group, identified in 63% of the fishes examined, followed by Digenea (47.4%), Monogenea (45.4%), Cestoda (19.5%) and Acanthocephala (14.4%).

Forty-eight species of Nematoda were recorded and nine of them were found in new hosts (Table 1): Cucullanus sp. (if), Goezia sp., Ichthyouris laterifilamenta Moravec, Kohn and Fernandes, 1992, Paracamallanus amazonensis Ferraz and Thatcher, 1992, *Procamallanus* (*Procamallanus*) annipetterae Kohn and Fernandes, 1988, Procamallanus (Spirocamallanus) inopinatus Travassos, Artigas and Pereira, 1928, *Procamallanus* (Spirocamallanus) sp., Raphidascaris (Sprentascaris) mahnerti (Petter and Cassone, 1984) and *Rondonia rondoni* Travassos, 1920 (if).

Thirty four species of Digenea were recovered, 11 of them in new hosts (Table 1): Crassicutis cichlasomae Manter, 1936, Dadaytrema oxycephala (Diesing, 1836), Dendrorchis sp., Genarchella astyanactis (Watson, 1976), Genarchella tropica (Manter, 1936), Magnivitellinum simplex Kloss, 1966, Paralecithobohtrys brasiliensis Freitas, 1947, Prosthenhystera obesa (Diesing, 1850), Saccocoelioides godoyi Kohn and Fróes, 1986, Saccocoelioides magnus Szidat, 1954 and Saccocoelioides nanii Szidat, 1954.

Eighteen species of Cestoda and ten of Acanthocephala were found in hosts already reported. Forty-four of the 98 species of fishes examined were parasitized with Monogenea and will be published in a later paper. The species of Acanthocephala referred herein were subject of a master thesis and are referred in another paper (Lopes et al. 2011).

Some morphological and taxonomical data based on these materials have already been published by Baptista-Farias et al. (2001), Cohen and Kohn (2008a, b), Cohen and Kohn (2009) Cohen et al. (2001), Fernandes and Kohn (2001), Kohn and Fernandes (1994; 2006), Kohn et al. (1995; 1999; 2000; 2003), Lopes et al. (2011) and Moravec et al. (1990; 1992a, b, c; 1993 a, b, c; 1994 a, b; 1997).

The Medium Paraná River underwent a great impact when changing from a lotic to a lentic environment. In addition, the natural barrier known as Sete Quedas was eliminated, because it was submerged in the reservoir when the Itaipu Dam was built. Thus, fish species that

had only lived in Sete Quedas (Guaira) below were able to climb and explore a new environment.

The floodplain of the Upper Paraná River was considered the last free stretch of the Paraná River. However, it has undergone severe changes in its system of flood and drought, since hydroelectric plants were built upstream and now control the water level of the river. Considering these changes, all the fauna, including the parasites of fishes, may be affected. Oscillations in the hydrologic flow, such as occur in floodplains, may influence the occurrence and size of fish parasite infrapopulations (Dogiel 1970). All these observed impacts on the floodplain can directly and indirectly affect the parasitic fauna of fish. Endoparasites, which typically have a complex life cycle, can be affected by changes in environments where the intermediate hosts live. Some species of the organisms that can serve as intermediate hosts may be favored and others may even be eliminated from the environment. Ectoparasites, those which are in direct contact with the environment, suffer directly from the changes caused by these impacts.

In the Medium Paraná River, 78 fish species out of 98 examined were parasitized by helminths. Nematoda was the most prevalent group, present in 63% of the fishes examined, followed by Digenea (47.4%), Monogenea (45.4%), Cestoda (19.5%) and Acanthocephala (14.4%). Since 1986, in the floodplain of the Upper Paraná River, 72 fish species have been examined and 278 species of helminths were recorded as parasitizing these. Monogeneans were identified with the largest number of species (95), followed by Digenea (73), Nematoda (71), Cestoda (47) and Acanthocephala (18). A checklist of fish hosts and their parasites was published recently by Takemoto *et al.* (2009).

In general, nematodes exhibit a low degree of host specificity. According to Eiras et al. (2010), the nematode Procamallanus (Spirocamallanus) inopinatus has already been identified in 51 fish species in Brazil. In the Medium Paraná River, P. (S.) inopinatus confirmed a low degree of host specificity and was identified in 15 species of fish (Astyanax bimaculatus bimaculatus, A. b. lacustris, Brycon orbignyanus, Catathyridium jenynsii, Crenicichla haroldoi, Leporellus vittatus, Leporinus copelandii, L. friderici, Pterodoras granulosus, Serrasalmus marginatus, S. spilopleura, Trachydoras paraguayensis, Tracheliopterus galeatus, Pimelodus sp. and Potamotrygon motoro). In the floodplain of the Upper Paraná River, this species was recorded in 10 host species (Hoplias aff. malabaricus, Leporinus elongatus, L. obtusidens, L. lacustris, Metynnis lippincottianus, Pseudoplatystoma corruscans, Serrasalmus marginatus, S. maculatus, Schizodon borellii and *Trachydoras paraguayensis*). Among all these species, only S. marginatus and T. paraguayensis were common in both environments studied.

Immature forms of nematodes of the family Anisakidae (Contracaecum sp., Hysterothylacium sp. and Anisakidae gen. sp.) were found in 24 fish species examined in the localities studied on the Medium Paraná River. In the floodplain of the Upper Paraná River, 17 hosts were reported to be parasitized by Contracaecum and/or Hystherothylacium larvae. Species of the Anisakidae deserve special attention; they parasitize fish as larvae, using them as intermediate or paratenic hosts and are known to be agents of parasitoses in humans. However, to date, no reports of such zoonotic diseases have been made in the region. This is probably because the parasites are large and mainly parasitize the mesentery, which is not used as food by people.

Some species of Digenea also exhibit a low degree of host specificity. The metacercariae of Austrodiplostomum compactum, parasitic in the eyes of fish, were recorded for the first time in *Plagioscion squamosissimus* from the reservoir of the Hydroelectric Power Station of Itaipu by Kohn et al. (1995). In the floodplain, this larva was reported in the same host species by Pavanelli et al. (1997), as well as in some other host species: Hoplias aff. malabaricus, Satanoperca pappaterra, Crenicichla britskii, Cichla kelberi (= Cichla monoculus), Cichlasoma paranaense (Machado et al. 2005). Yamada et al. (2008) also reported it as parasitising Hypostomus regani, Schizodon borellii, Serrasalmus marginatus and Auchenipterus osteomystax. This parasite is very common in the "corvina" P. squamosissimus. Machado et al. (2005) reported a prevalence of 95% and recorded 397 parasites in one fish. Due to this high prevalence, this trematode species was probably introduced together with its definitive host.

The prevalence was also relatively high in *S. pappaterra* (71.9%) and in *C. kelberi* (65%). This parasite is ecologically important since it lives in the eyes of fish, damaging their vision and making them susceptible to predators. Thus, the parasite can complete its life cycle.

Among the hosts examined, 47 helminth species were common in both sampling sites. However, fishes from the Upper Paraná River floodplain showed a greater species diversity of helminth parasites. This difference probably occurred because, despite all the above-mentioned changes that are occurring in the floodplain, all animals necessary for completing the life cycles of the respective helminths are present in this environment. In the Itaipu reservoir, the impact was greater following the impoundment and many organisms may have disappeared. Some of them may act as intermediate hosts of helminth parasites.

The differences in the taxonomic diversification of the parasite assemblages of different fish species were mainly related to the environment, trophic level and temperature (Luque and Poulin 2008). Therefore, the Upper Paraná River floodplain, characterized by the presence of a wide variety of habitats and species, favors the occurrence of a greater diversity of fish parasites.

TABLE 1. List of helminths of freshwater fishes recorded in reservoir of the Hydroelectric Power Station of Itaipu, Parana, Brazil. E/P = number of examined / parasitized hosts, I = number of infected hosts by each species, A = Acanthocephala, C = Cestoda, D = Digenea, M = Monogenea, N = Nematoda, if = immature form, mc = metacercariae.

TABLE 2. List of freshwater fishes not parasitized recorded in reservoir of the Hydroelectric Power Station of Itaipu, Parana, Brazil.

FISHES	COMMON NAME	N
Anostomidae		
Leporinus sp.	piau, piava	10
Schizodon altoparanae	piau	4
Schizodon nasutus	piau, timborê	1
Auchenipteridae		
Ageneiosus inermis [=A. brevifilis]	perna de moça	1
Ageneiosus ucayalensis	mandubé, mandi-leiteiro	1
Callichthyidae		
Callichthys callichthys	cascudinho, tamoatá	1
Characidae		
Moenkhausia intermedia	viuvinha	2
Cichlidae		
Oreochromis niloticus niloticus	tilápia	1
Tilapia rendalli	tilápia	1
Curimatidae		
Curimata sp.	papa-terra	1
Doradidae		
Rhinodoras dorbignyi	armado	1
Gymonotidae		
Gymnotus carapo	sarapó, morenita	1
Loricariidae		
Ancistrus cirrhosus	cascudo-roseta	2
Hypostomus luteomaculatus	cascudo-amarelo	2
Hypostomus margaritifer	cascudo	1
Hypostomus sp. 3	cascudo-tarzã	5
Parodontidae		
Parodon tortuosus	canivete	6
Pimelodidae		
Pimelodus fur	mandi-prata	1
Rivulidae		
Rivulus sp.	charuto	1
Sternopygidae		
Eigenmannia trilineata	tuvira	1

ACKNOWLEDGMENTS: The authors are grateful to the directorate of the "Itaipu Binacional", in special to the "Superintendência de Gestão Ambiental" and to the staff of the "Divisão de Reservatório", for the facilities offered to examine the fishes, to Mariana dos Santos Lopes from the "Laboratório de Helmintos Parasitos de Peixes, Instituto Oswaldo Cruz" for helping us both in field and laboratory. A. Kohn was supported by a research fellowship (I) and S.C. Cohen was supported by a research grant (no. 461719/2008-6) from the "Conselho Nacional de Desenvolvimento Científico e Tecnológico - CNPq."
